A series of new 4-aryl-1-(biarylmethylene)piperidines have been synthesized. They are structurally related to SLV-313, a potential atypical antipsychotic agent with potent D₂ receptor antagonist and 5-HT_{1A} receptor agonist properties. Suzuki-Miyaura reaction of cyclic vinyl boronates, derived from the vinyl triflates of *N*-protected tetrahydropyridines, with appropriate aryl halides yielded 4-aryl-piperidines. The reductive amination of the latter with suitable biarylaldehydes accomplished the synthesis of the new compounds.

Introduction

Schizophrenia is a complex lifelong chronic neuropsychiatric illness, afflicting approximately 1 % of the world population. The symptoms of the disease can be grouped as positive and negative. Positive symptoms include delusions, hallucinations, and conceptual disorganization. The most characteristic negative symptoms are affective flattening, social withdrawal, anhedonia, and poverty of thought and content of speech [1]. The typical antipsychotic drugs, for example haloperidol or chlorpromazine, were the most widely used drugs for this disease because they block D₂ receptors. However, although the blockade of D₂ receptors improves the positive symptoms, the development of neurological side effects such as dystonia, muscle rigidity, tremor and akathisia, and tardive dyskinesia, and in particular of extrapyramidal side effects (EPS) [2, 3] undermine compliance. Various atypical or second-generation antipsychotics, such as clozapine and more recently aripiprazole have been developed to reduce EPS liability and to treat negative symptoms. The atypical antipsychotics combine D₂ receptor antagonism with activity at other receptors such as serotonergic receptors, on the premise that a suitable balance of pharmacological activity should broaden the spectrum of therapeutic efficacy and reduce EPS. It has been demonstrated that the combination of a dopamine D₂ receptor antagonist with 5-

HT_{1A} receptor agonist properties could improve the therapeutic window, side-effect profile and therapeutic efficacy of antipsychotic agents [4]. As a result adoprazine (**1**) (SLV-313) and bifeprunox (**2**), possessing potent D₂ receptor antagonist and 5-HT_{1A} receptor agonist properties, were developed [5]. However, the failure of **1** and **2** to oppose phencyclidine-induced social interaction deficits suggested that an appropriate 'balance' of activity at these sites is necessary for activity in this model [4]. Thus, the need to discover compounds having varying ratios of D₂ and 5-HT_{1A} activities continued [6]. This report describes the synthesis of a series of new 4-aryl-1-(biarylmethylene)piperidines **3a–f**, **4a–f** and **5a–f**, structurally related to **1** (Fig. 1).

Results and Discussion

The synthesis of compounds **3a–f**, **4a–f** and **5a–f** required the synthesis of aldehydes **6b–f**. Suzuki reaction of 4-bromobenzaldehyde with 4-fluoroboronic acid yielded **6b** whereas the reaction between 5-bromonicotinaldehyde (**7**) with the appropriate boronic acid gave the desired aldehydes **6c** and **6d** [7–10]. The known aldehydes **6e** and **6f** were synthesized from their corresponding bromides **8** and **9** by employing literature-known procedures [11] (Scheme 1).

The synthesis of the required arylpiperidines was commenced from lithiation of **10** in THF at –78 °C fol-

lowed by quenching with *N*-protected piperidinone **11** to obtain alcohol **12** in 68 % yield. The dehydration of the latter was ensued by refluxing it in concentrated HCl and MeOH to generate compound **13** in a moderate yield. To produce the desired intermediate **4** from compound **13**, removal of *N*-protection and reduction of the double bond were required. Hence compound **13** was subjected to hydrogenation in a Parr apparatus at 60 psi (1 psi = 6894.757 Pa) for 5 h. The benzyl deprotection, however, proved to be stubborn, and the

reaction yielded a mixture of products which were difficult to separate (Scheme 2).

Thus, the desired intermediates **4** and **5** were synthesized by an alternative route as outlined in Scheme 3. Suzuki-Miyaura reaction of cyclic vinyl boronates **14** [12], derived from the vinyl triflates of *N*-protected tetrahydropyridines, with bromoquinoline **10** generated compound **15**. Hydrogenation of intermediate **15** in a Parr apparatus at 50 psi for 6 h followed by column-chromatographic purifications on silica gel produced intermediates **16** and **17** in a ratio of 3 : 7. Exposure of compounds **16** and **17** to trifluoroacetic acid at room temperature smoothly furnished the desired intermediates **4** and **5** in high yields (Scheme 3).

Likewise, to synthesize the required intermediate **3**, Suzuki-Miyaura reaction of cyclic vinyl boronates **14** with bromoquinoline **18** [13] generated compound **19**, which in turn was hydrogenated at 50 psi for 7 h to furnish intermediate **20**. Exposure of the latter to trifluoroacetic acid at r. t. smoothly produced the desired intermediate **5** in an overall yield of 36 % from **18** (Scheme 4).

Scheme 5. Synthesis of 1-aryl-4-(biaryl-methylene)piperidines **3a–f**, **4a–f** and **5a–f**, a representative example.

Having the desired arylpiperidines **4** and **5** and biarylaldehydes **6b–f** in hand, we next performed the reductive amination in 1,2-dichloroethane, using $\text{NaBH}(\text{OAc})_3$ as reducing agent to obtain the desired piperidines **3a–f**, **4a–f** and **5a–f** (Scheme 5).

Conclusion

In conclusion we have accomplished the synthesis of a series of new 1-aryl-4-(biaryl-methylene)piperidines, **3a–f**, **4a–f** and **5a–f**, structurally related to SLV313.
